Trust spatial data before analysis

GeoQA Atlas is a public WebGIS demo for GeoQA. It turns validation output into a map first review surface that non expert GIS users can understand in minutes.

Profiles

Focused

Review style

Map first

- Explain what GeoQA checks before analysis, reporting, or delivery.
- Show map evidence, issue groups, and suggested next steps in one product layer.
- Keep deterministic validation in the GeoQA Python engine while Atlas handles presentation.

POWERED BY GEOQA

Trust your geospatial data before analysis.

GeoQA Atlas turns GeoQA reports into map-first QA review workflows for layers, attributes, and delivery risk.

Desktop first

Demo datasets with real review flows

Atlas presents public demo datasets as practical review workspaces, with counts, profiles, geometry type, issue totals, and a direct path into the map.

Feature types

Lines

Feature types

Polygons

Feature types

Points

- Roads, boundaries, parcels, places, and utility examples show different QA patterns.
- Each card explains the use case before opening the full review surface.
- Public copy stays concise so non expert GIS users can orient quickly.

Map-first issue review

Review spatial findings on a readable map, inspect grouped issue cards, and move from problem to action without exposing private delivery data.

Issue drawer

Grouped findings keep repeated issues readable while preserving counts and examples.

Report JSON

Raw report access remains available for technical users and reproducible review.

GeoQA

The Python engine stays the source of truth while Atlas explains the result visually.

QA evidence

Clear next steps

Map first issue review

The dataset workspace places the map and problem drawer at the center. Users can inspect raw layers, issue overlays, summary cards, top issue types, and report downloads without reading raw JSON first.

Report JSON

GeoQA

- Issue groups keep repeated findings readable while preserving total counts.
- Show on map links focus the selected feature or the best available issue geometry.
- Cleaned layer controls stay disabled unless a real cleaned geometry layer exists.

No public arbitrary upload

GeoQA source of truth

Run QA on selected local layers

Atlas can preview uploaded GeoJSON and zipped Shapefile deliveries. For multi layer ZIPs, users select the layer to check so the app does not imply that the entire archive passed validation.

Validation

Python

Exports

JSON

- Profile choices are filtered by geometry type to reduce confusing options.
- Public demo mode checks a bounded subset and labels that scope clearly.
- Future all layer validation can call the GeoQA Python backend without duplicating validators in JavaScript.

What Atlas is for

A polished public-facing demo that helps people understand GeoQA in under five minutes.

For portfolio review

Shows a finished product layer with map evidence, issue explanations, and a clear GeoQA brand story.

For GIS teams

Demonstrates how validation findings become reviewable decisions instead of hidden report rows.

For delivery workflows

Makes layer scope, issue counts, downloads, and next steps visible before handoff.

Atlas is the review layer. GeoQA remains the deterministic Python validation engine.
